Signatures of Cosmic Reionization on the 21cm 3-Point Correlation

Kai Hoffmann

collaborators: Yi Mao, Houjun Mo

Motivation

Why going beyond second-order statistics?

3-point correlations are sensitive to **additional information** on

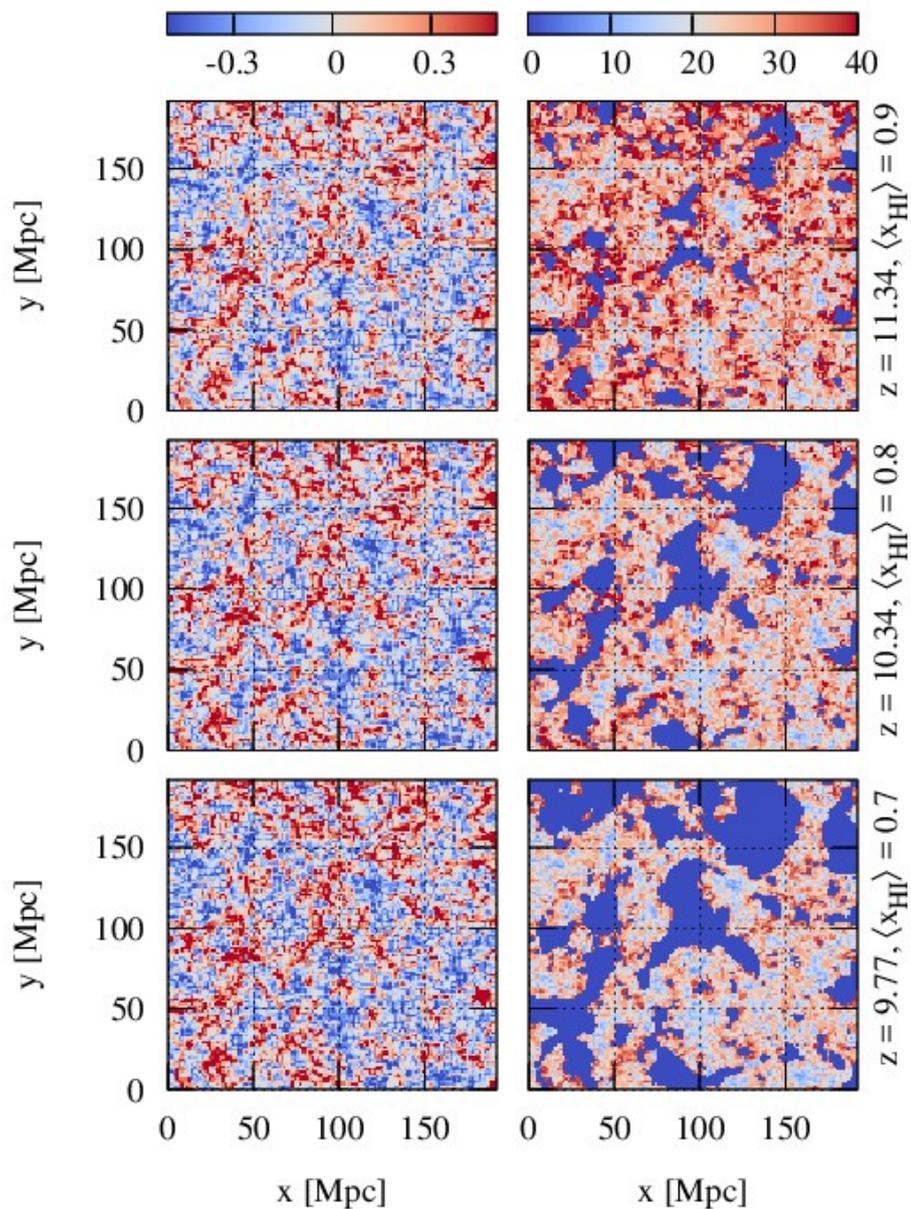

- **Non-Gaussianity** and **shape of fluctuations** in 21cm brightness temperature
- coming from **bubble morphology** and the underlying **large scale structure** (see Suman Majumdar et al. 2017, arXiv:1708.08458)

→ **21cm 3pc can tighten constraints**

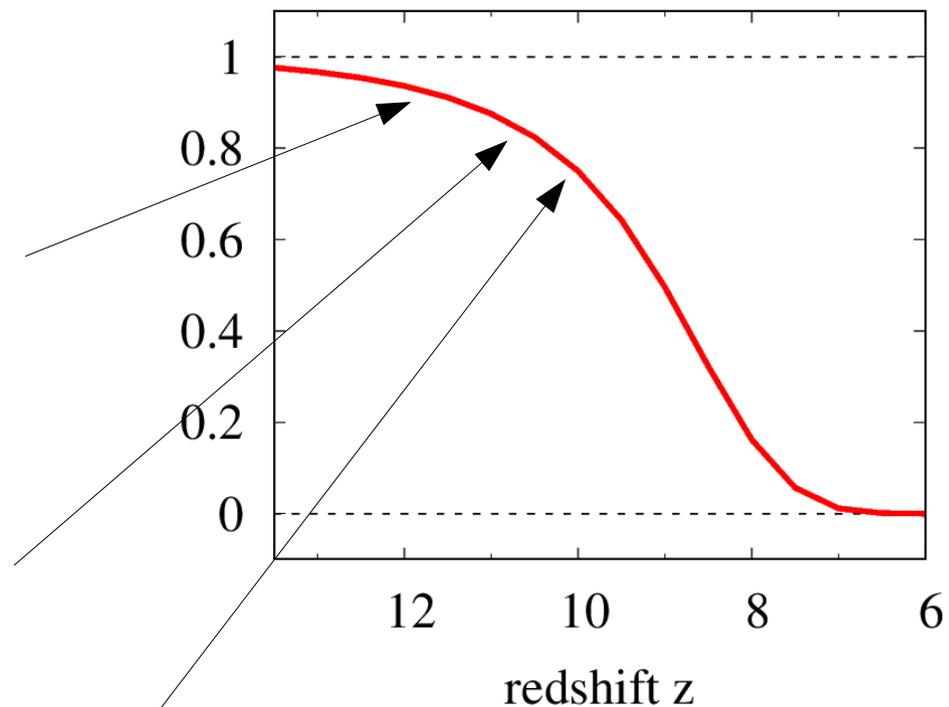

- on Reionization models (*see Shimabukuro et al. 2017, 1608.00372*)
- possibly on cosmological models (see conclusions)

21cmFast simulations

matter 21cm brightness
fluctuations Temperature [mK]

Global neutral fraction

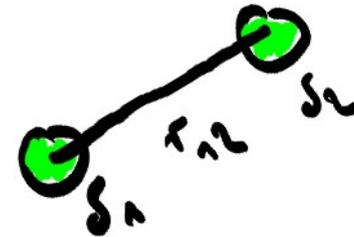

- $(768 \text{ Mpc})^3$ box
- 200 realizations

2- and 3-point correlations

fluctuations: $\delta \stackrel{\text{def}}{=} \frac{\rho - \bar{\rho}}{\bar{\rho}}$

2-point correlation (2pc):

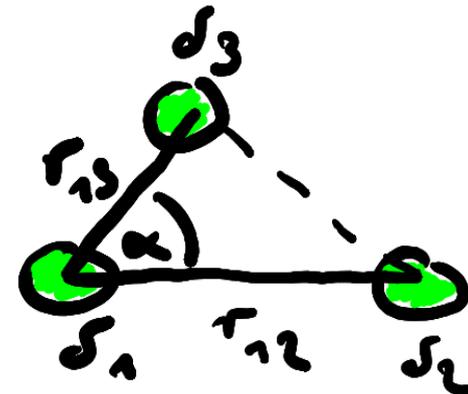

$$\xi \stackrel{\text{def}}{=} \langle \delta_1 \delta_2 \rangle (r_{12})$$

- spherically symmetric \rightarrow not sensitive to shape of fluctuations

3-point correlation (3pc):

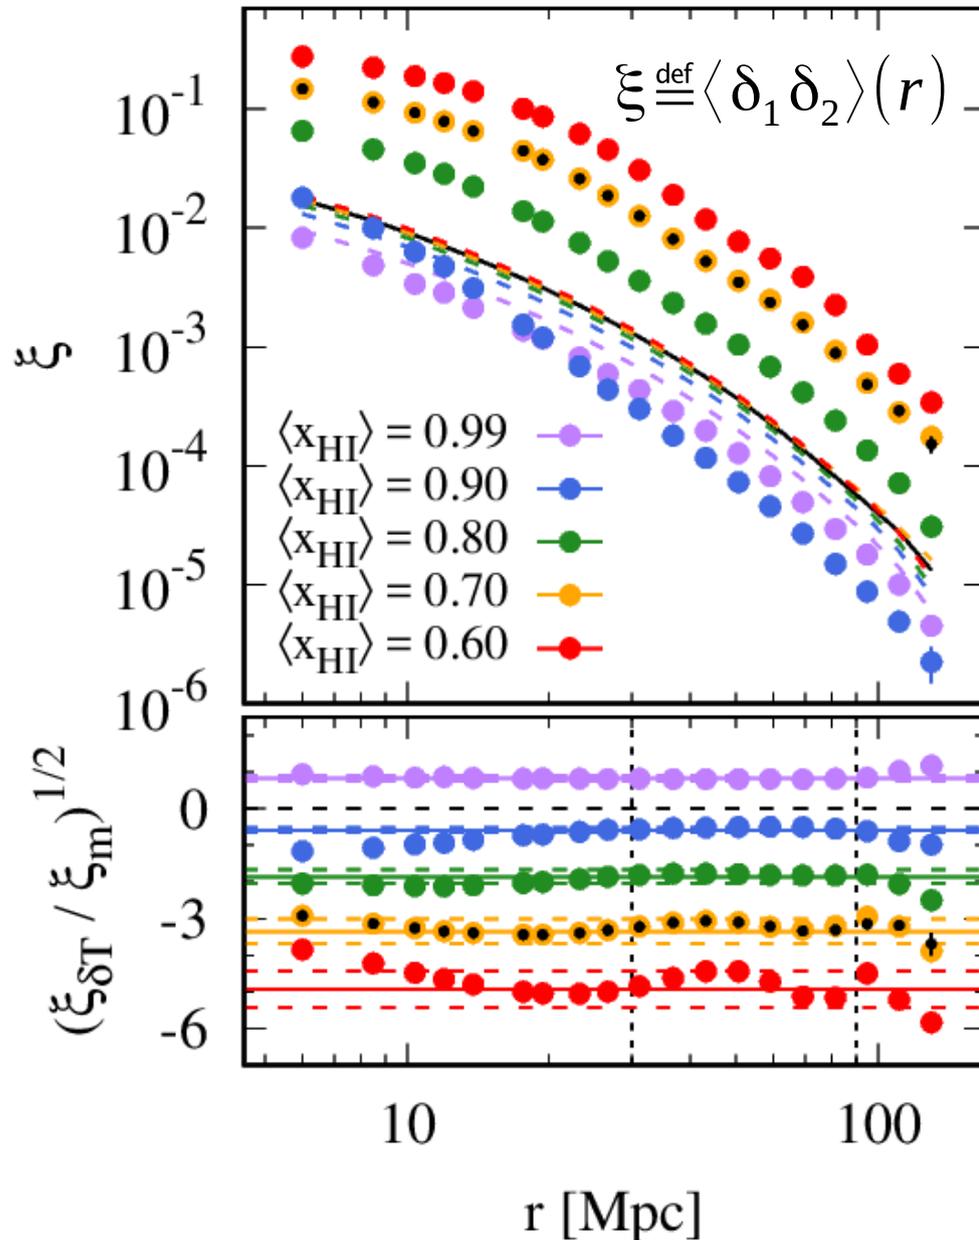

$$\zeta \stackrel{\text{def}}{=} \langle \delta_1 \delta_2 \delta_3 \rangle (r_{12}, r_{13}, \alpha)$$

- provides additional shape info

2pc measurements - 21cm vs matter

means over 200 realizations

Lines: matter

Dots: 21cm brightness temperature

large scale approximation at early times:

$$b_1 \approx \sqrt{\xi_m / \xi_{\delta T}}$$

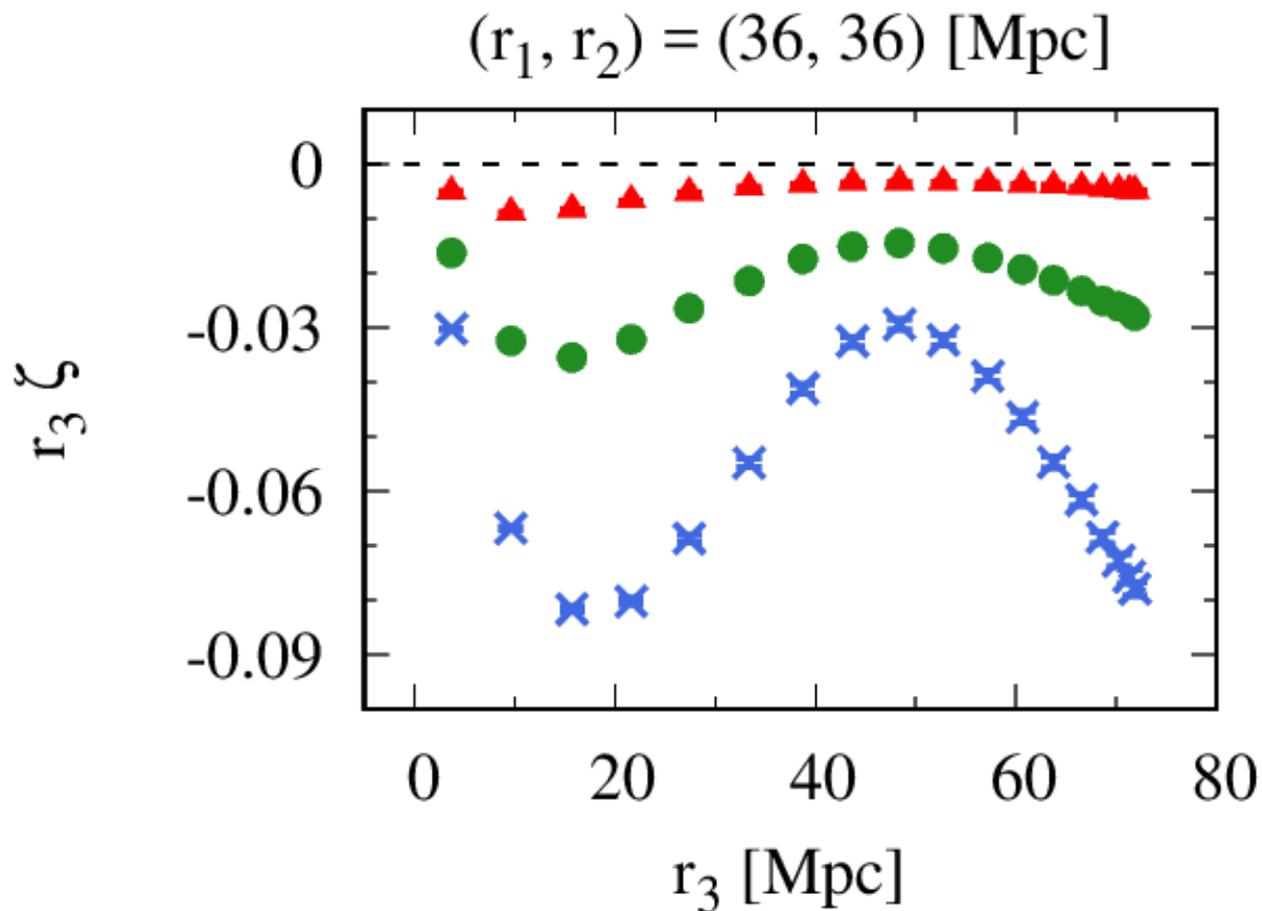

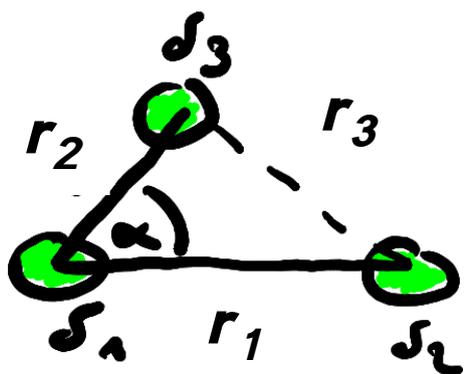

Linear bias b_1 :

- positive at early times
- negative at late times

fits between $30 < r < 90$ Mpc

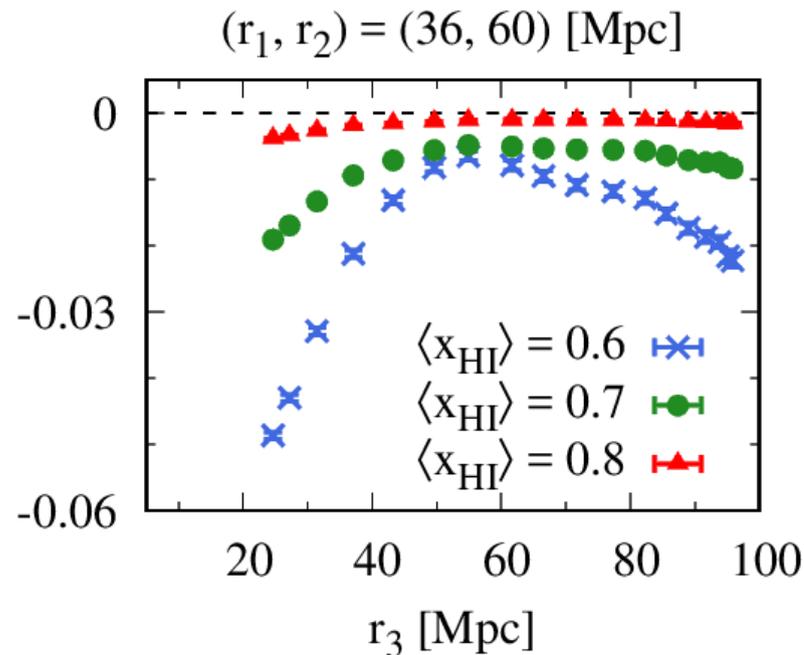

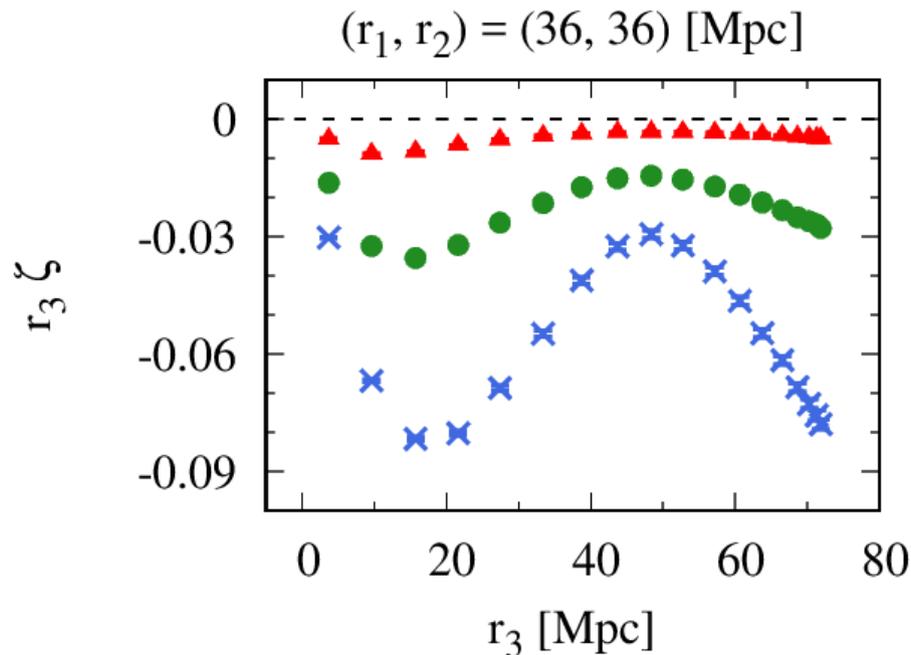

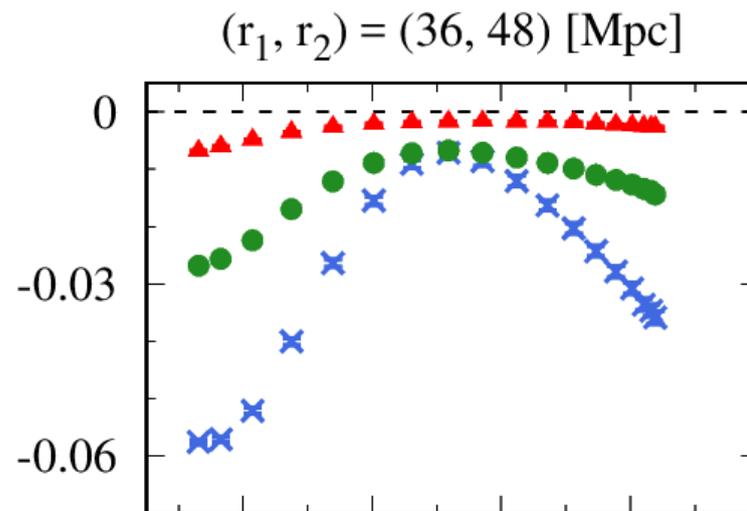

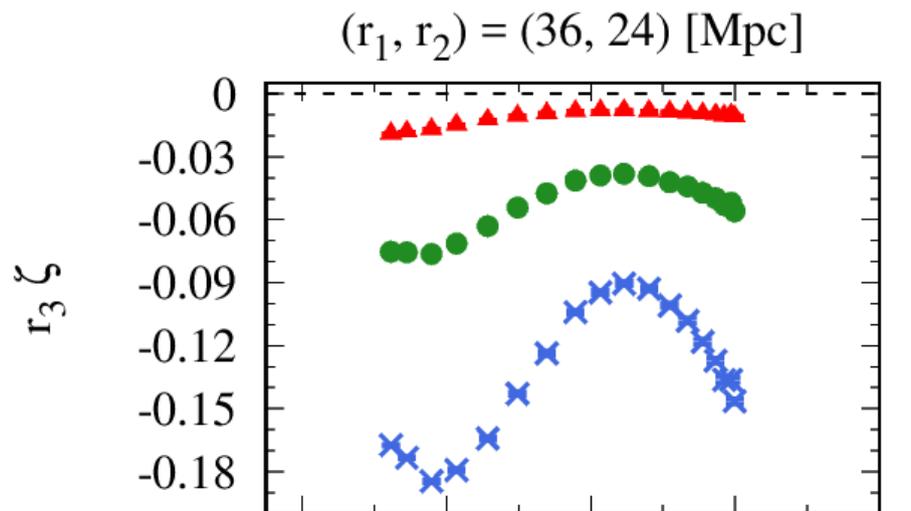

21cm 3pc scale and z dependence

$$\zeta \stackrel{\text{def}}{=} \langle \delta_1 \delta_2 \delta_3 \rangle$$

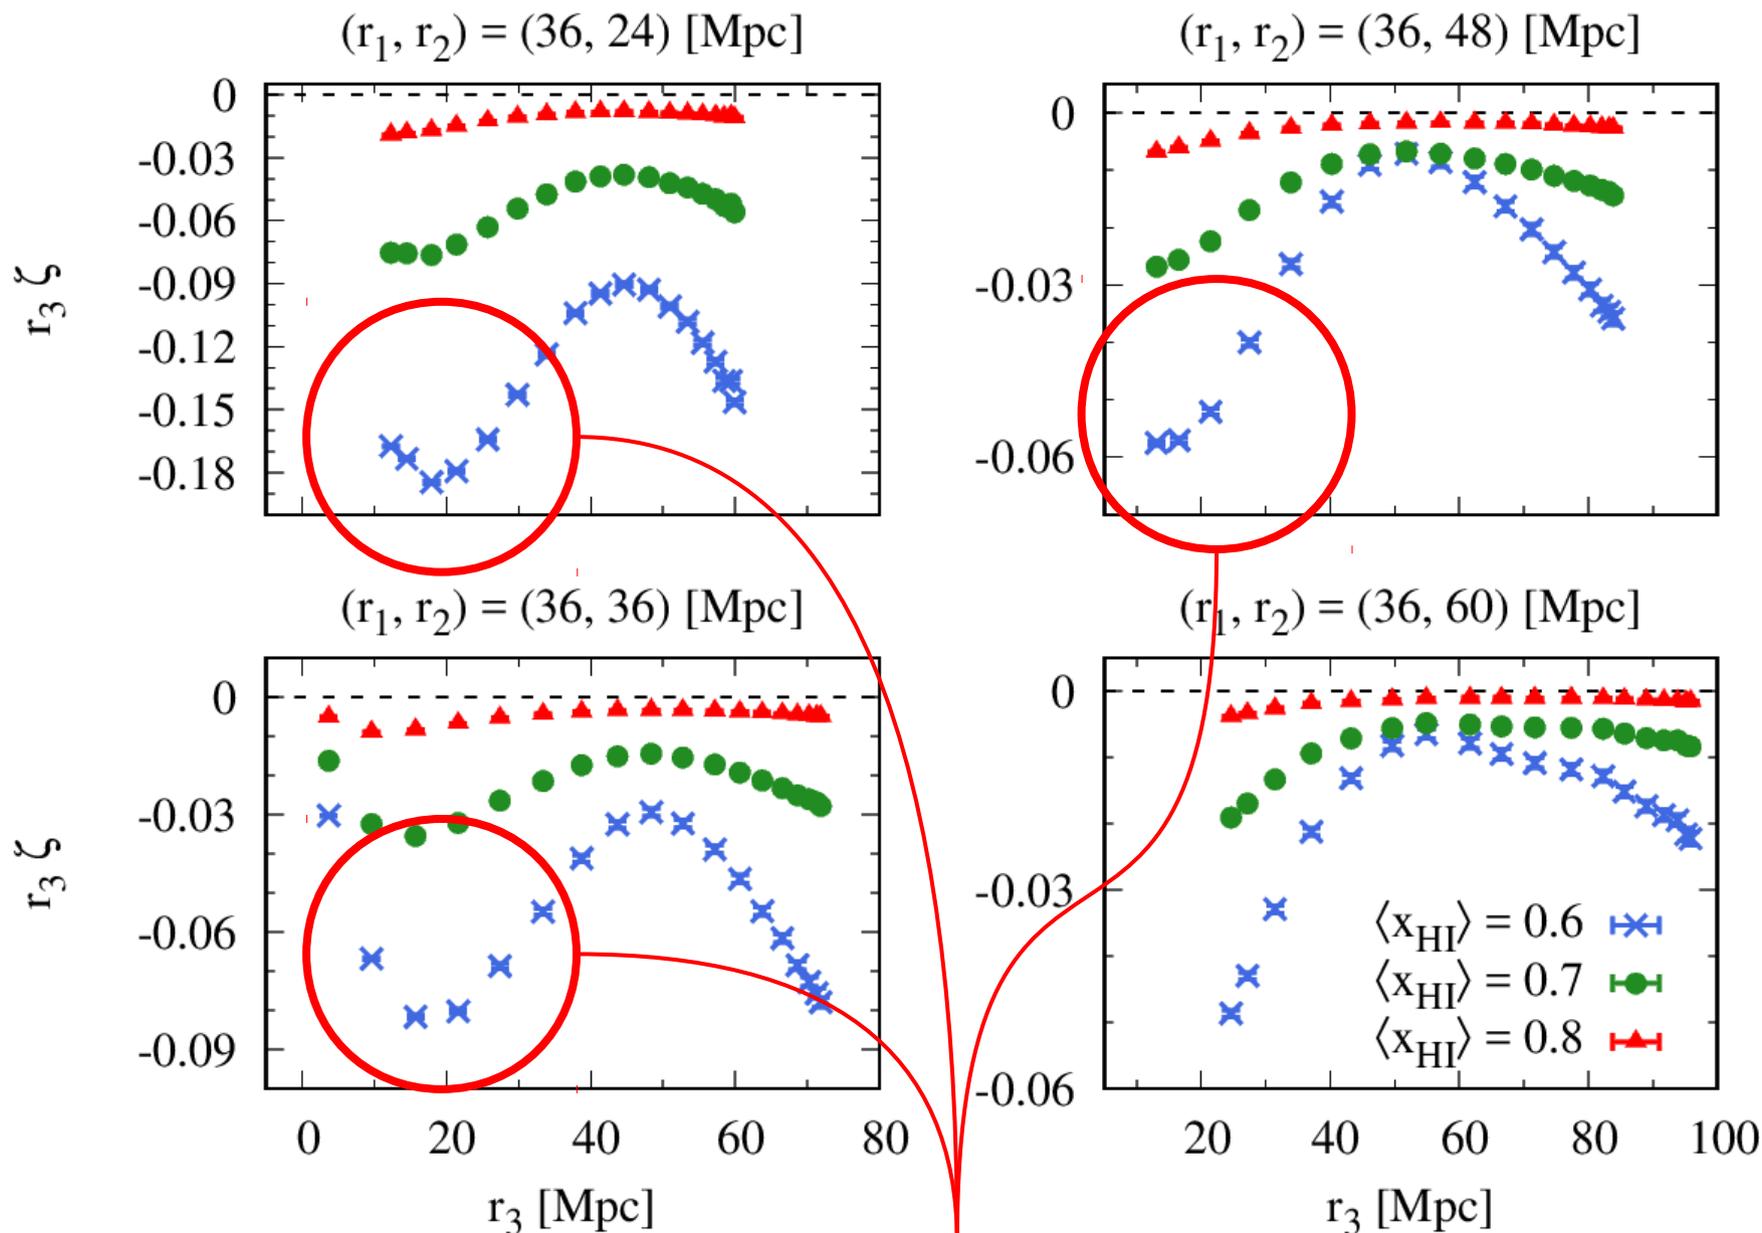

(means over 200 realizations)

21cm 3pc scale and z dependence

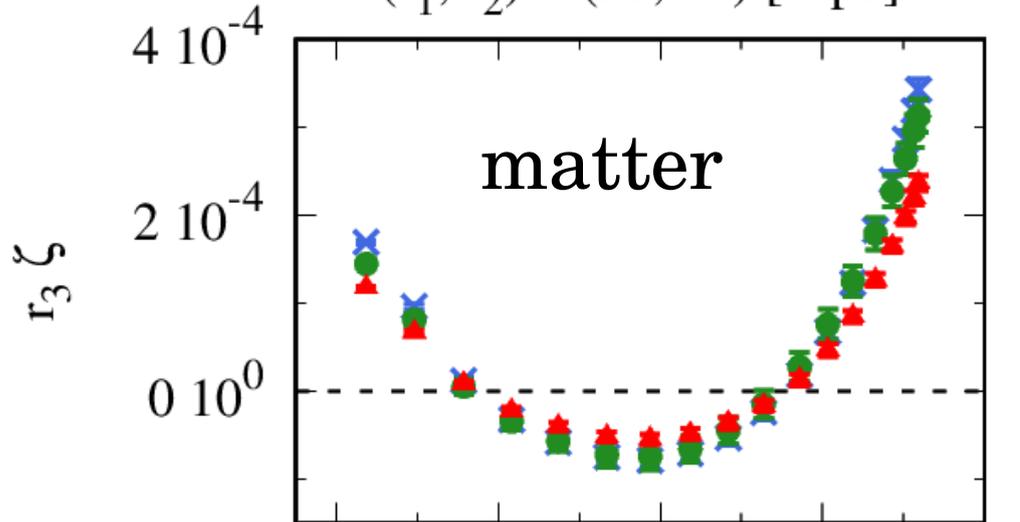

21cm 3pc scale and z dependence

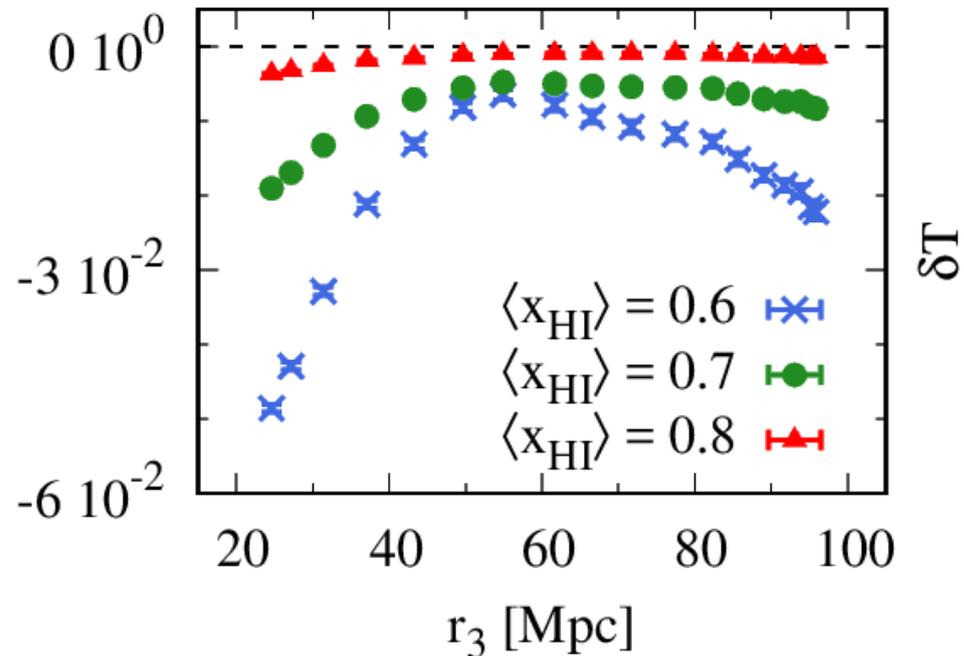

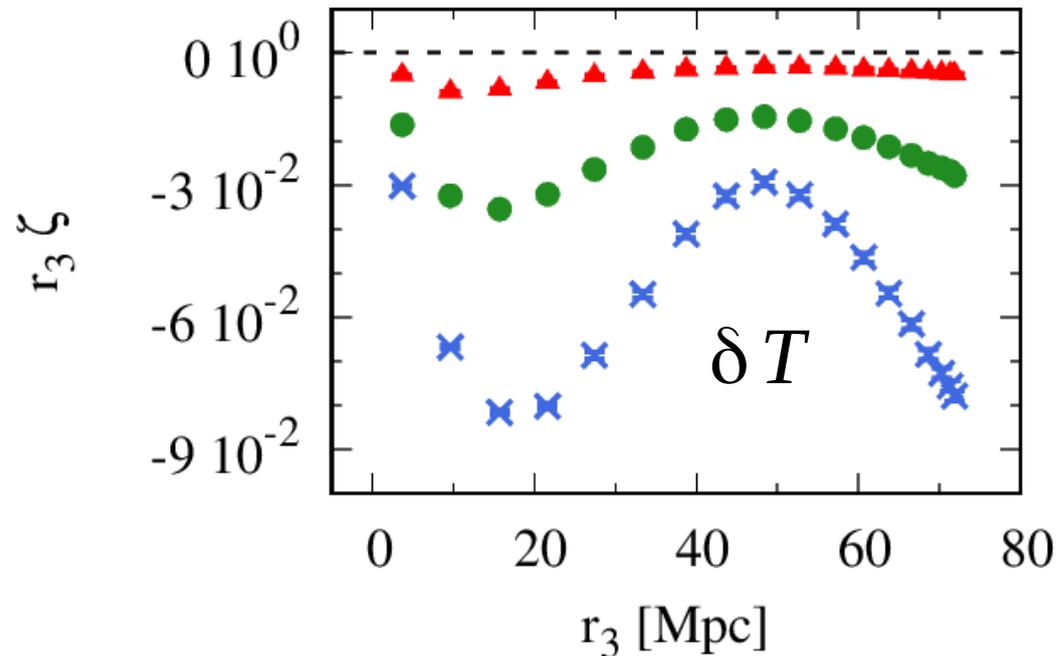

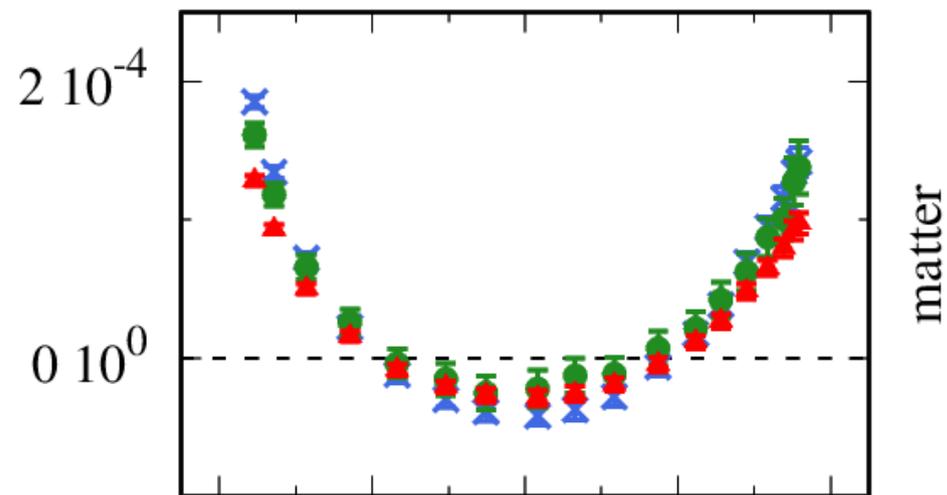

signitures of HII bubbles at $r < 20$ Mpc

3pc - 21cm vs matter

$(r_1, r_2) = (36, 24)$ [Mpc]

$(r_1, r_2) = (36, 48)$ [Mpc]

quadratic bias model

$$\delta_{\delta T} = F(\delta_m) \approx b_1 \delta_m + b_2 (\delta_m^2 - \sigma_m^2)$$

introduced for LSS tracers by Fry&Gaztanaga 93

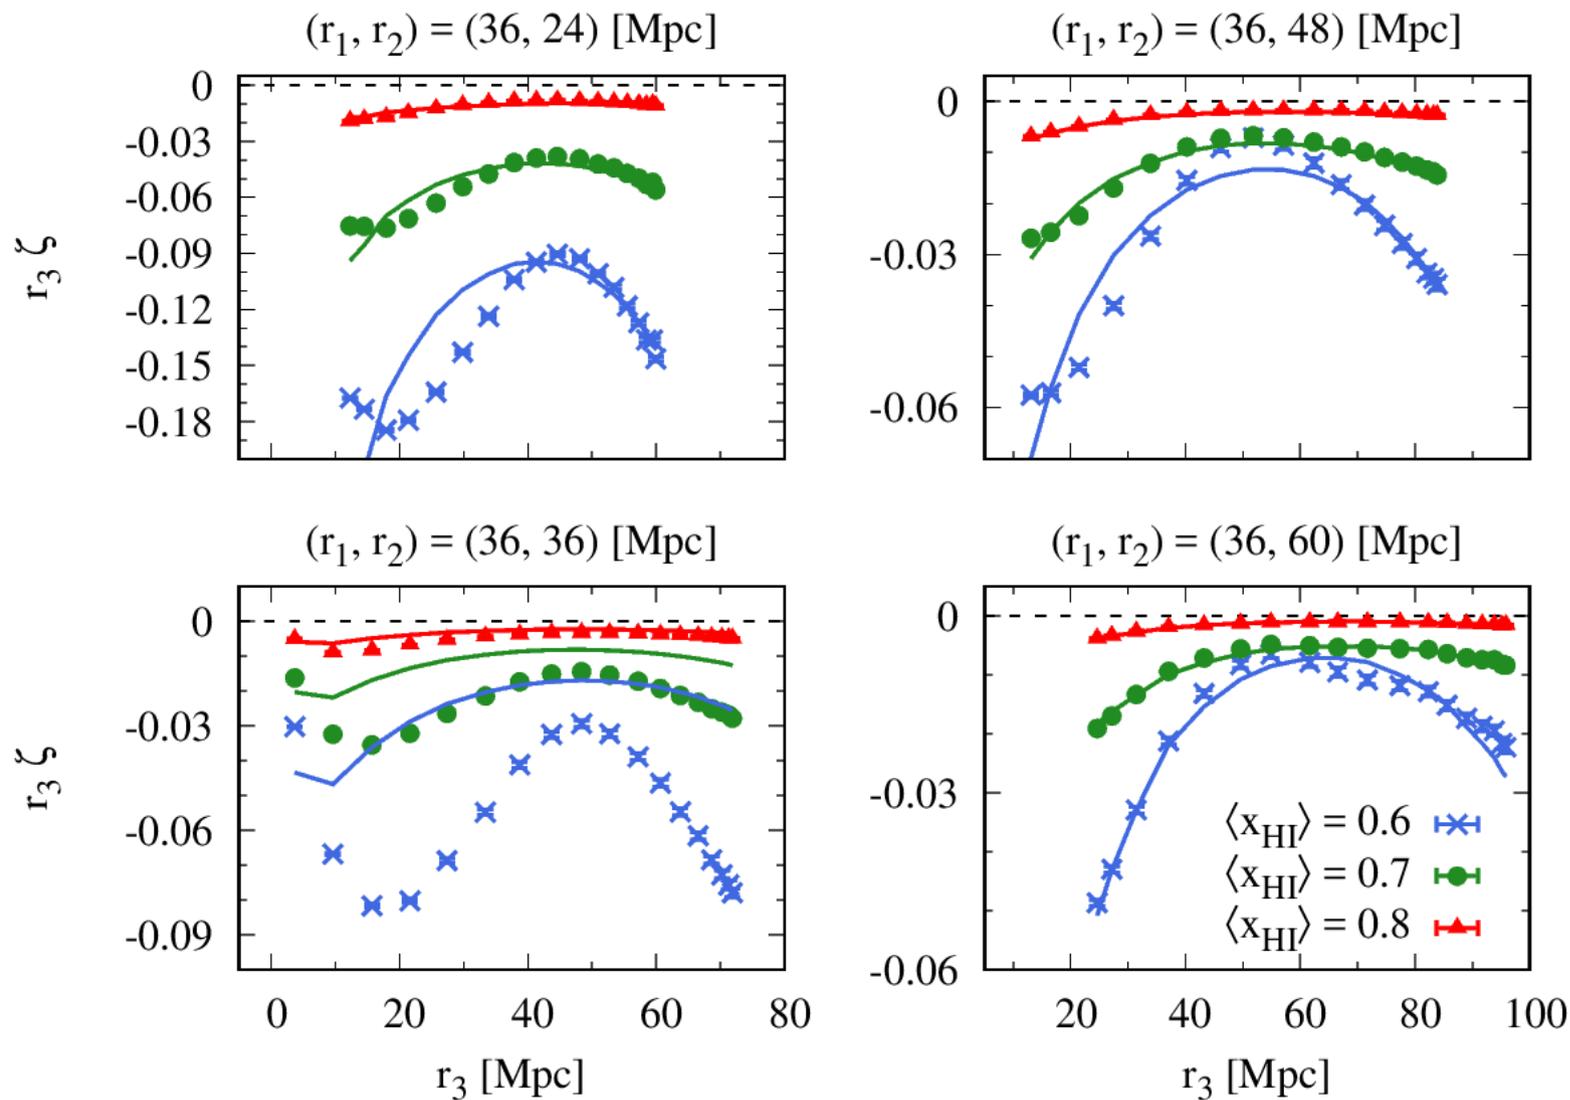

Assumption: 21cm brightness temperature is deterministic function of underlying matter density

Leading order approximations of correlation functions:

2pc $\xi_{\delta T}^{(12)} \approx b_1^2 \xi_m^{(12)}$

3pc $\xi_{\delta T}^{(123)} \approx b_1^3 \xi_m^{(123)} + b_1^2 b_2 (\xi_m^{(12)} \xi_m^{(13)} + 2 \text{ perm.})$

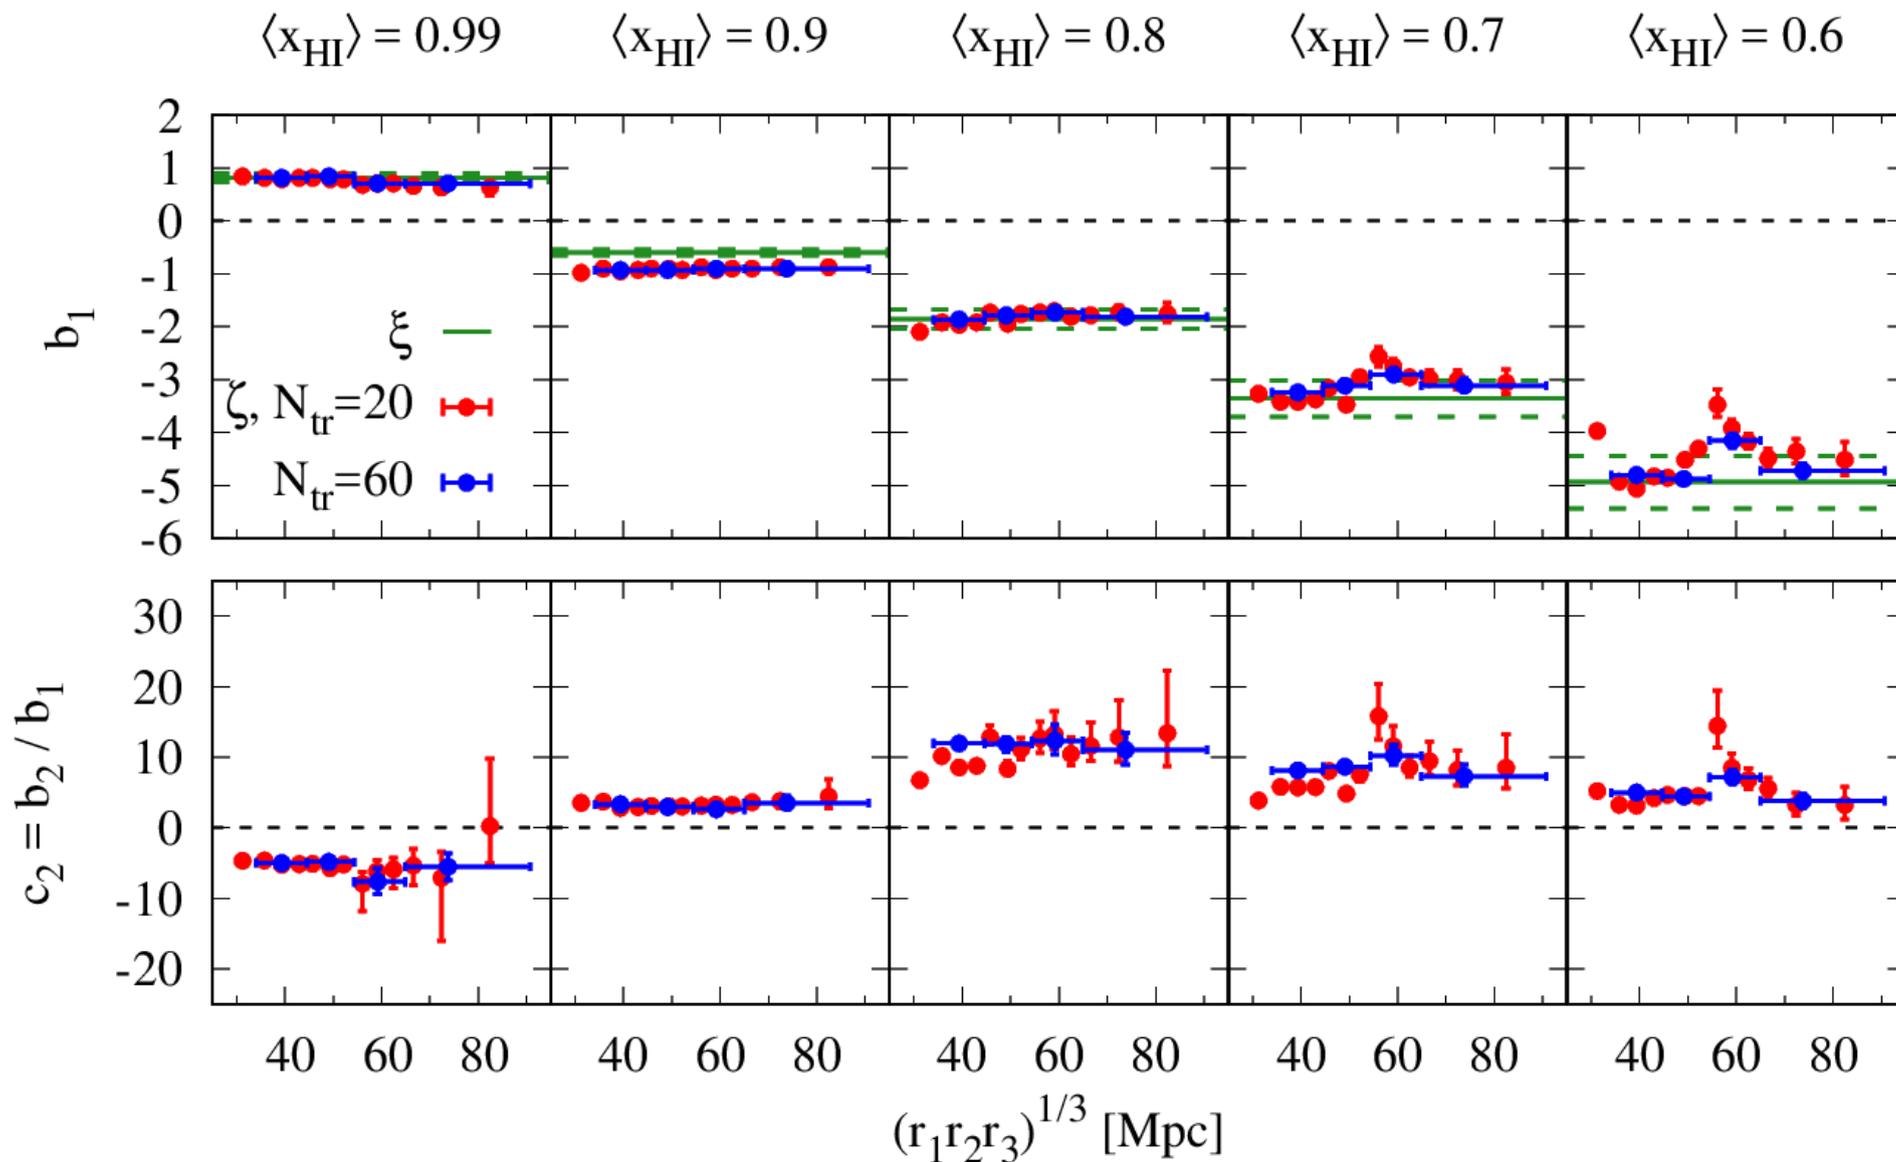

21cm 3pc fits

Fitting model $\zeta_{\delta T}^{(123)} \approx b_1^3 \zeta_m^{(123)} + b_1^2 b_2 (\zeta_m^{(12)} \zeta_m^{(13)} + 2 \text{ perm.})$

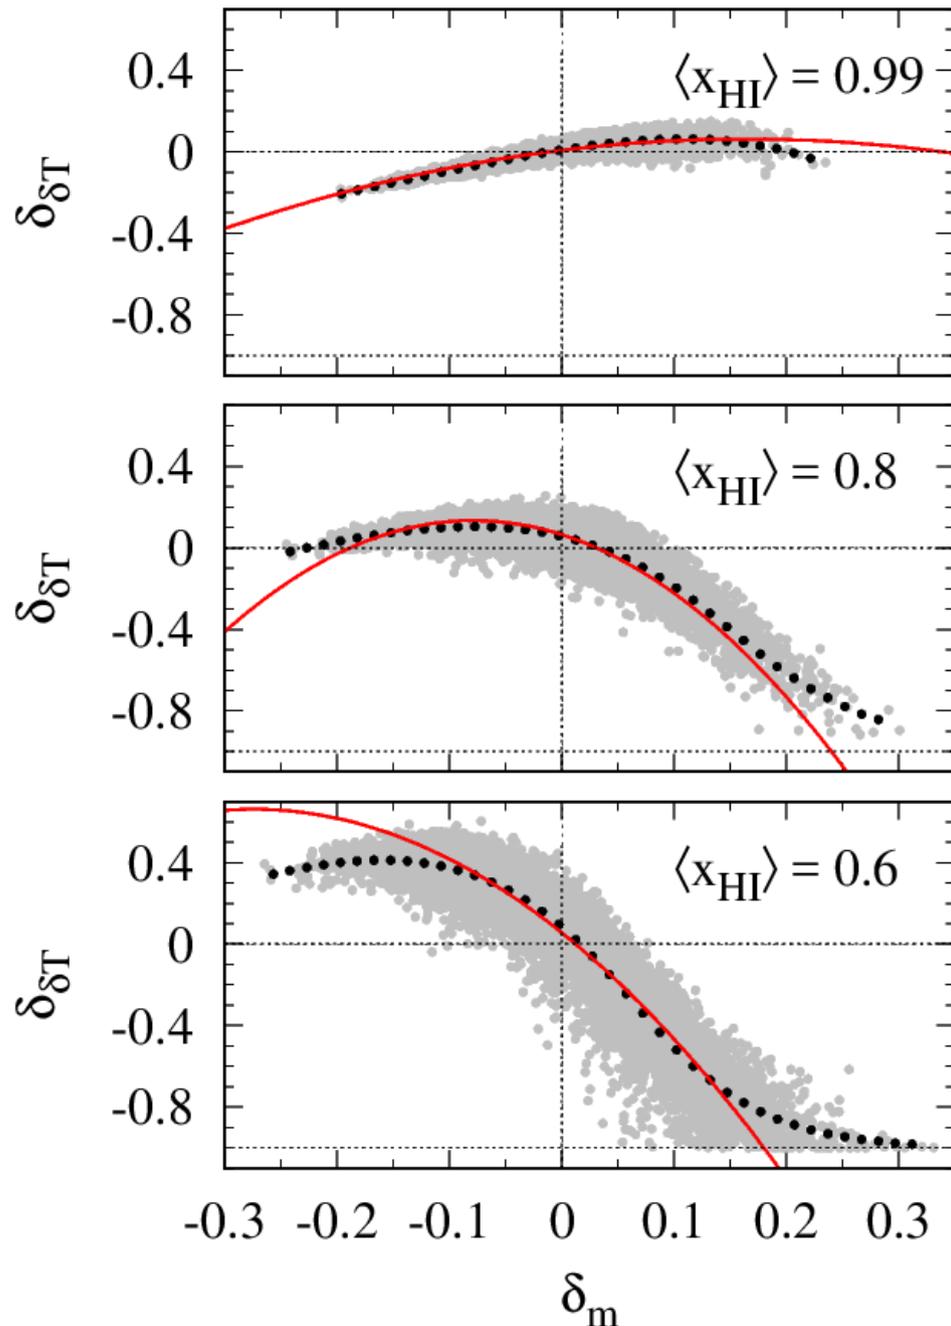

Bias comparison 3pc vs 2pc

Joint analysis of 240 striangle

Consistent linear bias measurements from 2pc and 3pc

Bias comparison

- grey dots: fluctuations in 24 Mpc cubical grid cells in one realization
- black dots show mean over 200 realizations
- red lines show predictions from quadratic bias model with b_1 and b_2 from 3pc measurements

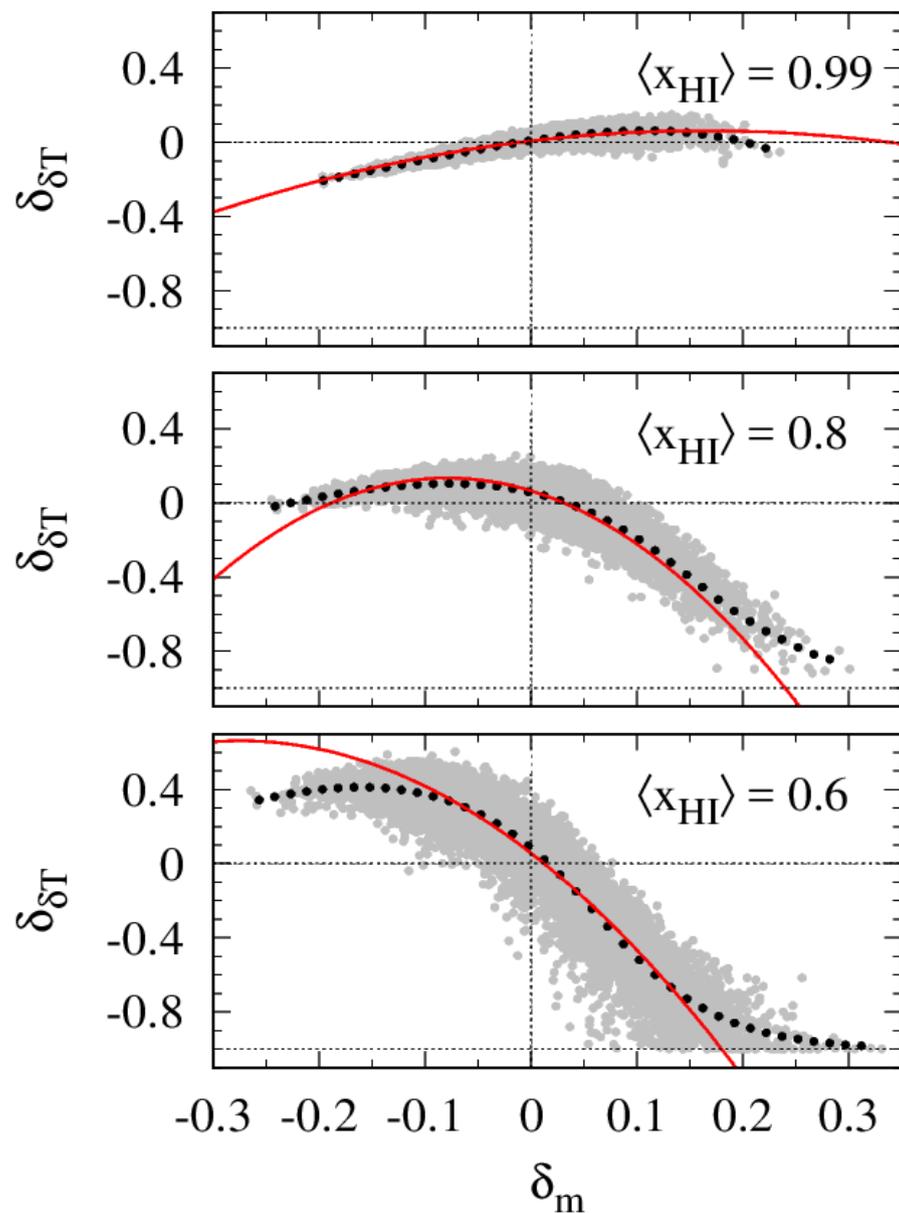

$$\delta_{\delta T} \approx b_1 \delta_m + b_2 (\delta_m^2 - \sigma_m^2)$$

Linear bias (slope):

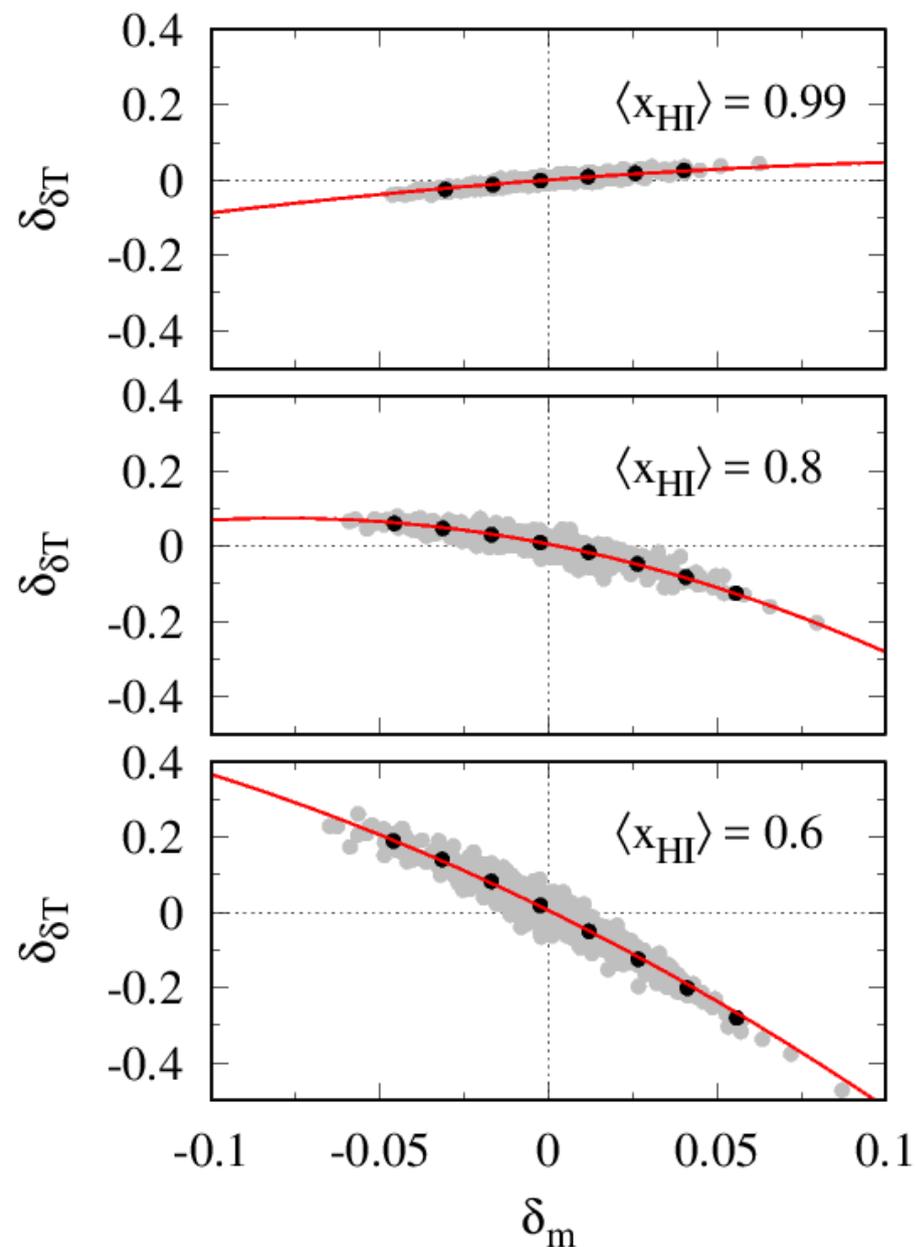

- positive at early times
- negative at late times

Bias comparison

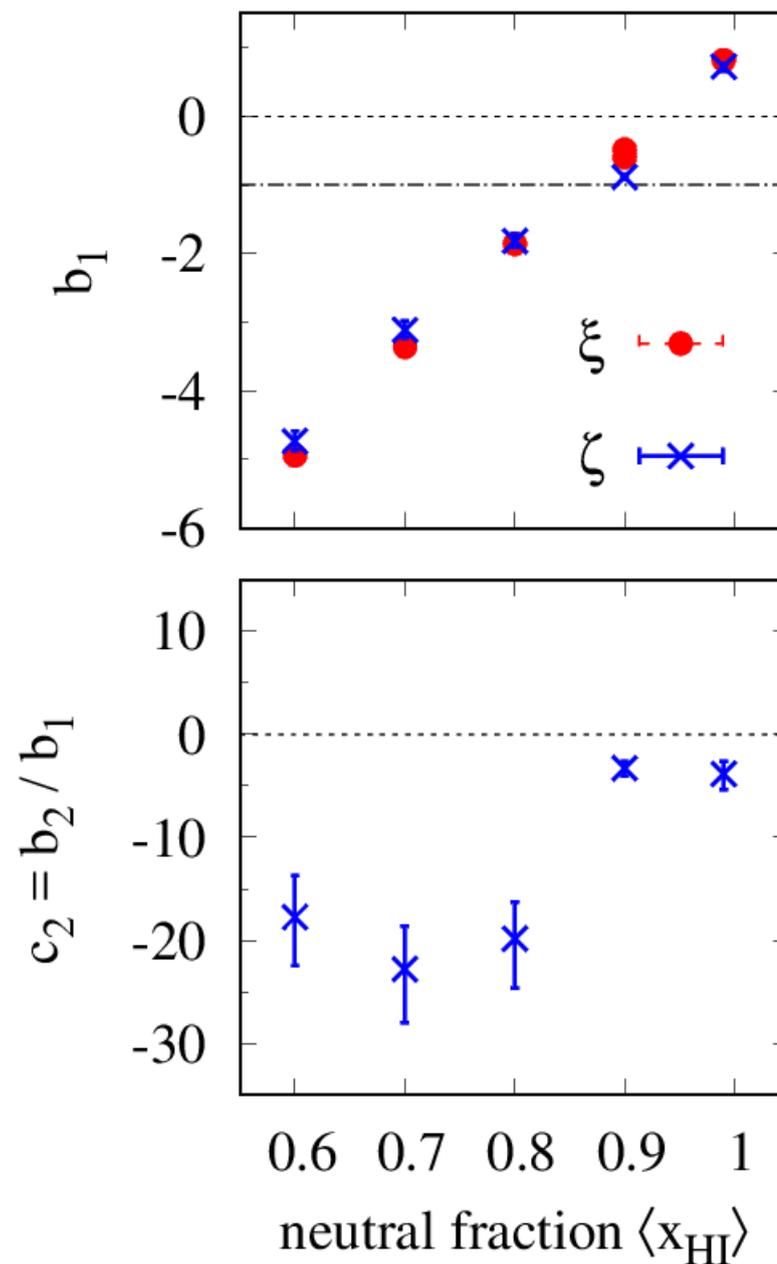

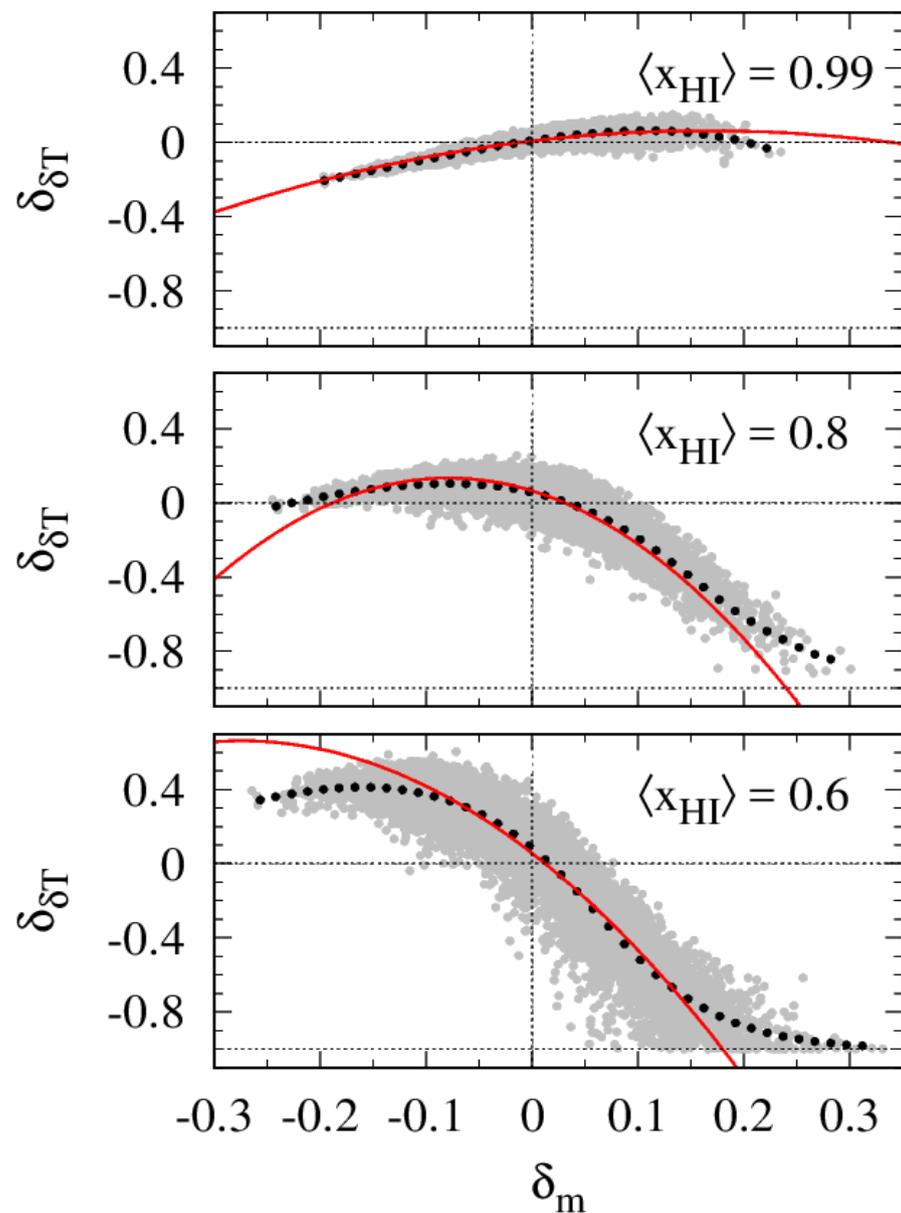

24 Mpc smoothing

96 Mpc smoothing

Bias comparison

Summary & conclusions

- Quadratic bias model provides explanation for shape of 21cm 3pc at large scales and early times of reionization (neutral fraction $> 60\%$, $r > 20$ Mpc)
- Linear bias from 2pc and 3pc model fits to measurements consistent at 10% level, except for $|b_1| \sim 0$, where b_1 switches sign
- b_1 and b_2 measurements might allow for extracting physical information on EoR from 21cm observations
- Combining 21cm 2pc and 3pc can break growth-bias degeneracy
→ new possibility for cosmological constraints at high z

growth-bias degeneracy:
$$\xi_m^{(z)} = \xi_m^{(z_0)} D^2(z) / D^2(z_0)$$

Summary & conclusions

- Quadratic bias model provides explanation for shape of 21cm 3pc at large scales and early times of reionization (neutral fraction $> 60\%$, $r > 20$ Mpc)
- Linear bias from 2pc and 3pc model fits to measurements consistent at 10% level, except for $|b_1| \sim 0$, where b_1 switches sign
- b_1 and b_2 measurements might allow for extracting physical information on EoR from 21cm observations
- Combining 21cm 2pc and 3pc can break growth-bias degeneracy
→ new possibility for cosmological constraints at high z

growth-bias degeneracy:

$$\frac{D(z)}{D(z_0)} = \frac{b(z_0)}{b(z)} \sqrt{\frac{\xi_{\delta T}^z}{\xi_{\delta T}^{z_0}}}$$
